### Indications for Provincially Funded Vaccine

**Rotax®**

- Healthy infants starting immunization at 2 months up to and including 19 weeks (19 weeks 6 days) of age.
  - Vaccine will routinely be offered at the 2 and 4 month immunization appointments.
  - Healthy, non-hospitalized **preterm infants** can receive this vaccine based on their chronological age. Rotavirus vaccine may be considered for hospitalized infants in consultation with the infant’s physician specialist and the Infection Control professionals in the facility.

**RotaTeq®**

- Healthy infants starting immunization at 2 months up to and including 14 weeks (14 weeks 6 days) of age.
  - Vaccine will routinely be offered at the 2, 4 and 6 month immunization appointments.
  - Healthy, non-hospitalized **preterm infants** can receive this vaccine based on their chronological age. Rotavirus vaccine may be considered for hospitalized infants in consultation with the infant’s physician specialist and the Infection Control professionals in the facility.

### Schedule

**Rotax®**

- To determine schedule for infants expecting **Solid Organ Transplant (SOT)**, see Standard for Immunization of Transplant Candidates and Recipients #08.304.

**Routine Schedule:**

- **Dose 1** – 2 months of age
  - The first dose **must not** be administered to children who are:
    - less than 6 weeks of age
    - 20 weeks of age or older when starting their immunization.

- **Dose 2** – 4 months of age and at least 4 weeks **after** dose 1
  - Ideally the second dose should be administered by 24 weeks of age, but if immunization is delayed, the second dose must be administered **before** 8 calendar months of age.

**Notes:**

- To optimize protection, vaccine series should be completed by following the routine schedule as closely as possible.
- If the first dose of rotavirus vaccine is inadvertently given to an infant older than the maximum age for first dose, the MOH/MOH designate should be consulted.

**RotaTeq®**

- To determine schedule for infants expecting **Solid Organ Transplant (SOT)**, see Standard for Immunization of Transplant Candidates and Recipients #08.304.

**Routine Schedule:**

- **Dose 1** – 2 months of age
  - The first dose **must not** be administered to children who are:
    - less than 6 weeks of age
    - 15 weeks of age or older when starting their immunization.

- **Dose 2** – 4 months of age and at least 4 weeks **after** dose 1
  - Ideally the second dose should be administered by 24 weeks of age, but if immunization is delayed, the second dose must be administered **before** 8 calendar months of age.

- **Dose 3** – 6 months of age and at least 4 weeks **after** dose 2. If any doses of the immunization series are delayed, the third dose must be completed **before** 8 calendar months of age, respecting the minimum interval between doses.

**Notes:**

- To optimize protection, vaccine series should be completed by following the routine schedule as closely as possible.
- If the first dose of rotavirus vaccine is inadvertently given to an infant older than the maximum age for first dose, the MOH/MOH designate should be consulted.
If an incomplete dose is administered for any reason (e.g., infant spits or regurgitates the vaccine), a replacement dose should not be administered.

Infants who have had rotavirus gastroenteritis should receive or continue to receive immunization.

The rotavirus vaccine series should be completed with the same vaccine product. However, if the product used for the first dose is not available or unknown, the vaccine series should be completed with the available product. If any dose in the series was RotaTeq® or is unknown, a total of three doses of vaccine should be administered.

Rotavirus vaccines may be administered concomitantly with or at any time before or after live parenteral vaccines.

Infants born to HIV positive mothers can safely receive rotavirus vaccine. The majority (greater than 99%) of these infants will not be infected with HIV. If they become infected, they do not become significantly immunocompromised until later in infancy (after rotavirus vaccine has been administered).

### Contraindications/

**Contraindications:**
- Known severe hypersensitivity to any component of the vaccine or its container.
- Anaphylactic or other allergic reaction to a previous dose of vaccine containing similar components.
- Infants with suspected or a known immunocompromising condition, except infants born to HIV positive mothers, must have a consultation with the infant’s physician specialist or expert in the condition prior to administration of the vaccine.
- Uncorrected congenital malformation (e.g., Meckel’s diverticulum) of the gastrointestinal tract that would predispose for intussusception.
- History of intussusception.
- Severe Combined Immunodeficiency Disorder (SCID), a rare inherited illness which affects the immune system.
- Infants with a known or suspected family history of congenital or hereditary immunodeficiency that is a contraindication to immunization with live vaccine should not receive rotavirus vaccine unless their immune competence has been established.

**Precautions:**
- Excretion of vaccine virus in the stools is known to occur after immunization and lasts for 10 days on average with peak excretion around the seventh day. Rotavirus vaccine may be administered to infants living in households with individuals who are immunocompromised. To minimize the risk of transmission of rotavirus vaccine virus, parents/caregivers should be counseled regarding the importance of hand washing particularly after diaper changes, before food preparation or direct contact with the immune compromised person.
- No safety or efficacy data are available for the administration of rotavirus vaccine to infants who have recently received immune globulins or other blood products. However, expert opinion supports administration of rotavirus vaccine at any time before, concurrent with or after administration of immune globulins or other blood products.
- Postpone vaccine administration for infants suffering from moderate or severe diarrhea or vomiting.
  - Infants with pre-existing chronic gastrointestinal conditions and not considered to be immunocompromised may be immunized.
- Cystic Fibrosis (CF) is not a contraindication to receiving rotavirus vaccine. Screening positive at birth for CF is not a contraindication. In both scenarios rotavirus vaccine is recommended.
There are no restrictions on the infant’s consumption of food or liquid, including breast milk, either before or after immunization.

Immunosuppressive therapy given to a mother during pregnancy or lactation can cause immunosuppression of infants. Please refer to the Standard on Immunization of Individuals with Chronic Health Conditions and/or Immunosuppression. Consultation with zone MOH/designate may be necessary to assess vaccine eligibility.

### Possible Reactions

#### Common:
- Fever
- Diarrhea and/or vomiting
- Irritability/fussiness
- Loss of appetite
- Cough/runny nose
- Otitis media

#### Uncommon:
- Bronchospasm
- Dermatitis
- Flatulence, abdominal pain
- Nasopharyngitis

#### Rare:
- Anaphylaxis
- Intussusception:
  - The overall incidence of intussusception remains rare. It has not been established whether rotavirus vaccine affects the overall risk of intussusception.
  - No increased risk of intussusception was observed during clinical safety trials. However, post-marketing safety studies indicate a small increased risk of intussusception after immunization, mostly within 7 days of the first dose and to a lesser extent after subsequent doses.

#### Note:
- Parents/guardians should be informed of the low risk of intussusception following rotavirus vaccine (1 to 7 cases per 100,000 doses), particularly during the 7 days following the first and to a lesser extent subsequent doses. Parent education should include the signs and symptoms of intussusception and the importance of seeking medical care should symptoms develop. They should also be informed that the risk of intussusception remains small compared to the benefit of rotavirus vaccination in preventing disease and the potential for severe diarrhea from rotavirus.

- As with any immunization, unexpected or unusual side effects can occur. Refer to the product monograph for more detailed information.

### Pregnancy

This vaccine is not intended for use in adults; therefore, no human data on use during pregnancy are available and animal reproduction studies have not been performed. Infants living in households with pregnant women should be immunized.

### Lactation

Infants who are breastfed should be immunized.

### Composition

**Rotarix®**

- Each 1.5 mL dose contains:
  - \(10^6.0\) CCID\(_{50}\) of human rotavirus RIX4414 strain, produced on Vero cells.
  - Dulbecco’s Modified Eagle Medium (DMEM)
  - Sucrose
  - Di-sodium adipate
  - Sterile water
  - Residual amounts of Porcine Circovirus type 1 (PCV-1).

**RotaTeq®**

- Each 2.0 mL dose contains:
  - Human-bovine rotavirus reassortants G1, G2, G3, G4, and P1A[8], produced on Vero cells, with a minimum dose level at the end of shelf life as follows:
    - G1 2.2 x 10^6 infectious units
    - G2 2.8 x 10^6
    - G3 2.2 x 10^6
    - G4 2.0 x 10^6
    - P1A[8] 2.3 x 10^6
  - Sucrose
## Rotarix® vs. RotaTeq®

### Program Notes:
- 2015 June 1 Rotavirus was introduced into the routine childhood immunization schedule in Alberta using Rotarix® vaccine. It was routinely offered at the 2 and 4 month immunization appointments.
- 2018 May 14 RotaTeq® was introduced into the routine childhood immunization schedule in Alberta.
